

# Node Lifecycle Hypothesis and the Crystallisation of 3D Space in CRF

Version 3: V20.3 Simulation Results

$\bar{d}_s = 3.031 \pm 0.076$  across three independent runs. Phase gap positive in all runs. Transfer rate reveals lossy crystallisation.

Ougit Jarittum

March 2026

## Abstract

CRF Hybrid V20.3 provides the most stable simulation evidence to date for the Node Lifecycle Hypothesis.

Three independent runs (N=500, 400 sweeps each) give:

$$\bar{d}_s = 3.031 \pm 0.076 \quad (\text{target } 3.0 \text{ from SO(3) proof})$$

The standard deviation has dropped from 0.233 (V20.2) to 0.076, indicating consistent convergence.

The phase test — comparing crystallised ( $\Omega$ -dominant) nodes against young (IDV-dominant) nodes — is positive in all three runs:

$$\Delta d_s = d_s^Y - d_s^X = 0.980 \pm 0.240 \quad (\text{positive in } 3/3 \text{ runs})$$

The per-collapse transfer rate measurement reveals a new finding: crystallisation is not a 1:1 exchange of IDV for  $\Omega$ . The measured ratio  $\Delta \text{IDV}/(-\Delta \Omega) = -2.212 \pm 0.015$  means that each R-event reduces IDV by approximately twice what it adds to  $\Omega$ . This is a *lossy* process: not all of the internal dimensional volume converts to mass — some possibility is simply relinquished.

Gravity  $R^2 = 0.9071 \pm 0.0010$ , the most stable value across all simulator versions, confirming that the wave and lifecycle extensions do not disturb the emergent gravitational law.

Five sub-hypotheses (HN-01 through HN-05) are updated with V20.3 evidence. HN-04 (Dimensional Hysteresis) is confirmed as a corollary of the SO(3) proof. The transfer rate finding motivates a revision of HN-01.

# 1 V20.3: Three Fixes and What They Revealed

V20.3 introduced three targeted improvements over V20.2:

## V20.3 Changes

**Fix 1 — Per-collapse transfer measurement:** Instead of tracking global  $\overline{V^{\text{int}}}$  and  $\overline{\Omega}$  per sweep, V20.3 records IDV and  $\Omega$  immediately before and after each R-event, giving a direct measurement of the transfer at the moment it occurs.

**Fix 2 — Absolute phase threshold:** Groups X (crystallised) and Y (young) are defined by absolute  $\Omega$  percentiles (70th and 30th), not the top/bottom 20%. This ensures the groups represent distinct lifecycle stages.

**Fix 3 — 8 trials for subgroup  $d_s$ :** The subgroup estimator uses 8 independent walk sets (was 3), giving  $\sim 800$  effective walkers per group and much lower variance in the phase gap measurement.

## 2 Core Results

### 2.1 Spectral Dimension

$$\$d_s\$ = 3.0310.076(3runs)$$

| Run            | $d_s$ (late mean)                   | Gravity $R^2$                         |
|----------------|-------------------------------------|---------------------------------------|
| 1              | 3.056                               | 0.9057                                |
| 2              | 3.110                               | 0.9076                                |
| 3              | 2.928                               | 0.9081                                |
| Mean $\pm$ std | <b><math>3.031 \pm 0.076</math></b> | <b><math>0.9071 \pm 0.0010</math></b> |

Comparison across simulator versions:

| Version                   | $d_s$                               | Gravity $R^2$ | Phase gap          |
|---------------------------|-------------------------------------|---------------|--------------------|
| V16 (canonical base)      | 3.008                               | 0.906         | —                  |
| V18 (IDV paper)           | 3.335                               | 0.908         | wrong direction    |
| V20 (Omega-metric)        | 3.238                               | 0.900         | +1.58 (1 run)      |
| V20.2 (continuous $d_s$ ) | $2.976 \pm 0.233$                   | 0.904         | +0.88 (3/4 runs)   |
| <b>V20.3 (this)</b>       | <b><math>3.031 \pm 0.076</math></b> | <b>0.907</b>  | <b>+0.98 (3/3)</b> |

## 2.2 Phase Test: Node Lifecycle Confirmed

### Phase Gap Positive in All Runs

Nodes split by  $\Omega$  level:

- Group X:  $\Omega \geq 70$ th percentile (crystallised)
- Group Y:  $\Omega \leq 30$ th percentile (young)

$$d_s^X = 3.08 \pm 0.22 \quad d_s^Y = 4.06 \pm 0.48 \quad \Delta = 0.980 \pm 0.240$$

All three runs:  $\Delta > 0$ .

Interpretation: crystallised nodes ( $\Omega$ -dominant) consistently reside closer to  $d_s = 3$  than young nodes (IDV-dominant). This is the central prediction of the Node Lifecycle Hypothesis, now supported in all simulation runs.

## 2.3 Transfer Rate: A New Finding

**Finding 1** (Lossy Crystallisation). The per-collapse transfer rate, measured directly at each R-event:

$$r = \frac{\Delta \text{IDV}}{-\Delta \Omega} = \frac{\text{IDV}_{\text{after}} - \text{IDV}_{\text{before}}}{-(\Omega_{\text{after}} - \Omega_{\text{before}})} = -2.212 \pm 0.015$$

(measured over 4663 collapse events per run).

Each R-event increases  $\Omega$  by  $\kappa = 0.15$  (fixed, from  $\text{mass} = 1 + \kappa \cdot N_{\text{eff}}$ ). The measured ratio means IDV decreases by  $\approx 2.2 \times 0.15 = 0.33$  per event — more than twice the  $\Omega$  gain.

Interpretation: crystallisation is not a 1:1 exchange. For every unit of  $\Omega$  (crystallised history) gained, approximately 2.2 units of IDV (accessible states) are lost. Some of the internal dimensional volume is simply relinquished — not converted to mass, but abandoned.

This is the CRF analogue of a thermodynamic efficiency  $< 100\%$ : the process of becoming actual costs more possibility than the actuality it creates.

## 3 Sub-Hypothesis Updates

### 3.1 HN-01 Revised: Lossy Phase Transition

The original HN-01 proposed  $F_i = H/(\Omega + \varepsilon_0)$  decreases at crystallisation (correct), but implicitly assumed a 1:1 IDV- $\Omega$  exchange.

The transfer rate finding revises this:

$$\Delta \text{IDV} \approx -\beta \cdot \Delta \Omega \quad \beta \approx 2.2 \text{ (measured)}$$

The free ratio at crystallisation satisfies  $\Delta F_i \approx -(1 + \beta)\Delta\Omega/(\Omega + \varepsilon_0)^2$ , falling faster than a 1:1 model predicts. The factor  $\beta$  is an empirical constant of V20.3 awaiting derivation from the  $\delta$ -chain.

### 3.2 HN-04: Confirmed as Corollary

**Corollary 1** (of SO(3) Proof). Dimensional hysteresis — once  $d_s \rightarrow 3$ , perturbation cannot restore a stable high- $D$  state — follows directly from Theorem 1 of CRF\_SO3\_Proof. Since  $n = 3$  is the unique  $\delta$ -stable dimension, no other stable attractor exists to receive a perturbation.

V20.3  $d_s$  oscillations (range 1.2–4.5 within runs) are consistent with this: the system fluctuates but the *late mean* remains near 3 in all runs.

## 4 Complete Status Table

| Code  | Statement                                 | Status           | Evidence                  |
|-------|-------------------------------------------|------------------|---------------------------|
| Core  | IDV-phase $\rightarrow$ $\Omega$ -phase   | Hypothesis       | V20.3 phase gap<br>3/3    |
| Core  | $d_s \rightarrow 3$ at crystallisation    | <b>Confirmed</b> | $3.031 \pm 0.076$         |
| Core  | Phase gap $\Delta > 0$                    | <b>Confirmed</b> | 3/3 runs                  |

## 5 What Remains Open

### Open: Derive $\beta \approx 2.2$ from $\delta$ -chain

The transfer ratio  $\beta = \Delta\text{IDV}/(-\Delta\Omega) \approx 2.2$  is empirical. It should be derivable from the IDV formula and the Born rule resolution step. Specifically: when P undergoes Dirichlet sampling, how much does  $H(P_i)$  decrease on average? The answer is a function of  $D_0$ ,  $\varepsilon_0$ , and  $k$ . This is the next formal derivation target.

### Open: P0 experiment

$G_{\text{sim}}/\ln 2 = 0.196\text{--}0.205$  across V20.3 runs. The gap to 1.0 requires measuring  $D_0$  in SI units through the P0 experiment ( $\tau_1 < \tau_2$  with SNSPD detectors). This remains the gate to Level 7/8 maturity.

*Crystallisation does not conserve possibility.  
For every unit of mass gained,  
more than two units of “could be” are released.  
The universe pays more than it receives —  
and what it receives is what we call matter.*
